

Individual Contribution Form

Abasiono Mbat · 24120111121 · Group G, Stream 1 · CYB 201 CA 1 — Project G: SQLi Dump + Covert Exfiltration · Submitted October 2026

1 · What I personally worked on

Item	Detail
My chain step	Person 2 of the attack chain: ran sqlmap against the target's SQLi page — confirmed the id parameter injectable via four techniques (boolean-based blind, error-based, time-based blind, UNION) and dumped the full users table (5 accounts, unsalted MD5 hashes). Recorded in my own terminal log.
My brief role	Documentation & Presentation: aggregated the group's evidence into the annotated report — captions, evidence-claim table, dev-team remediation list — and coordinated the figure/numbering pipeline.
Commands / tools	sqlmap (--technique=BETU, --dump), john (raw-MD5, rockyou.txt), steghide (embed/info/extract), nmap, curl, git.
What the results mean	User input is executed as SQL by the server; credentials are stored without salt, so a wordlist crack recovered every account in seconds; the extracted table can then be smuggled out hidden inside an ordinary JPEG.

2 · Peer review — what each teammate contributed (what I observed)

Teammate	Specific contribution	Evidence I observed
Miracle Chukwubuikem Nwachukwu (24120111059)	Ran the manual SQLi test by hand before any tool: baseline vs tampered request, raw MySQL error on the page; confirmed target service surface and stack.	The by-hand before/after screenshots in the group report (Figures 4–5) and the stack fingerprint from headers (Figures 2–3).
Akorede Ahmed (24120111007)	Hash-crack analysis: ran john with rockyou.txt against the dumped hashes, recovered passwords in seconds, pinned the unsalted-MD5 storage flaw (identical admin/smithy hash).	The john transcript with plaintexts in brackets (Figure 9 of the report).
Ayomide Fakayode (24120111043)	Ran the final chain stage live in the lab: steghide embed → verify → extract, including the troubleshooting pass left in the transcript on purpose.	The exfiltration run, verification close-up and file-manager screenshots (Figures 10–12 of the report).
Anjolaoluwa Bawaallah-Olufemi (24120111024)	Impact analysis: the blast-radius assessment in the report's impact section and inputs to the remediation list for the dev team.	The impact section and recommendation list of the group report.

3 · Peer participation scale (per the brief's 1-5 areas)

Member	Participation	Technical contribution	Collaboration	Reliability	Documentation
Miracle Chukwubuikem Nwachukwu	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent
Akorede Ahmed	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent
Ayomide Fakayode	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent

Anjolaoluwa Bawaallah-Olufemi	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent	5 — Excellent
----------------------------------	---------------	---------------	---------------	------------------	---------------

Scores are unanimous by agreement of the group: every member was up to the task, delivered their chain step promptly, and helped the others (for example, hands-on help with tool setup and transcript review during the steghide pass).

4 • Note for the instructor

Two of this member's situations worth flagging. First, my brief lists five roles for five people, but in practice I carried two: the report/documentation role and the sqlmap step of the chain (my laptop could not run the Metasploitable VM, so I rehearsed the same chain against a local practice target on my own machine — this is documented openly in the report's challenges section). Second, an early john run appeared to recover only 2 of 5 passwords; re-running it resumed and completed the remaining three — the interrupted-then-resumed sequence is preserved in my terminal log, since the guide says mistakes stay in the log.

Submitted alongside: my personal terminal log, named screenshots, and reflection (see the file list on the group report's evidence page).
